■ Unprotect

Unprotect[s1, s2, ...] removes the attribute Protected for the symbols s.

Unprotect["form1", "form2", ...] unprotects all symbols whose names textually match any of the form.

A typical sequence in adding your own rules for built-in functions is Unprotect[f]; definition; Protect[f]. See notes for Protect. See pages 196 and 566. See also: Protect, Locked, SetOptions.
